During Mist Elimination, it is very important to understand and apply the physics properly within various applications, e.g. a vane-pack may work properly under normal atmospheric conditions, but in a high-pressure hydrocarbon system, the physical properties of the system completely change, thus rendering conventional mist elimination devices practically useless at times. Also, in many debottlenecking and revamp cases within the gas, petrochemical and chemical industry, one comes across situations where capacity and separation performance are limited by the type of separation device chosen. This calls for innovative technologies; say for instance, separation of liquid droplets from the gas-liquid mixture by imparting higher centrifugal forces.

Liquid entrainment in a process gas stream can be formed by either dynamic processes such as contact between gas and liquid phases in a mass transfer operation or thermal processes such as condensation. Sulzer mist eliminators provide an effective solution to liquid entrainment problems in many types of equipment including scrubbing, absorption, stripping or distillation columns, evaporators, falling film condensers, knock-out vessels, three-phase separators, desalination plants, refrigeration plants, gas dehydration plants and compression systems. For best performance, it is important to achieve uniform gas flow distribution and maximum effective area. The most appropriate positioning is critical, in terms of disengagement distances from vessel inlet, outlet and other vessel internals.

For equipment based on direct and/or inertial interception, gas stream velocity affects all three principles involved in separation (impingement, coalescence and drainage). Flooding, or reentrainment of liquid, can occur if the flow of gas prevents drainage. The effective area of the mist eliminator is therefore established by determining an appropriate superficial velocity for the equipment using the well-known Souders Brown equation (1).

\[
v = K \cdot \sqrt{\frac{\rho_l - \rho_v}{\rho_v}}
\]

Sulzer KnitMesh™ Wire Mesh Mist Eliminators
Sulzer KnitMesh mist eliminators have an excellent track record as a low cost, highly versatile and efficient method of removing liquid entrainment from gas streams. They are produced as a bed of knitted mesh, which presents a tortuous path and large surface area to the droplets entrained in the gas stream. Separation is achieved by impingement on, and capture by, the filaments of the mesh where the droplets coalesce and drain (Figure 1). Installation can be made in a variety of ways but gas flow is usually either vertically upwards, with the liquid draining counter current to gas flow, or horizontal, with the liquid draining in a direction perpendicular to the gas flow. They provide excellent separation efficiency down
Chemical Engineering World

Gas velocity is so low that re-entrainment is limited. This simple enhancement to a standard mesh pad improves mist elimination because the higher velocities increase the droplets’ inertial impaction with the wires or filaments. In addition, the strategically placed collecting channels provide higher operational gas and liquid flow capacity (Figure 3).

**Sulzer Mellachevron**

Sulzer Mellachevron vane mist eliminators are high capacity inertial separators constructed as banks of parallel, chevron profiles, which cause the gas to change direction several times from inlet to outlet. Momentum forces entrained liquid droplets to impinge on the vane surfaces where they form a liquid film and drain. The Sulzer Mellachevron range is divided into a number of categories depending on direction of gas flow and the complexity of the vane profile.

**Combined Systems**

Increasing gas capacities and higher performance requirements in mass transfer equipment are challenging the capabilities of conventional mist eliminator equipment.
To solve this, Sulzer Chemtech offers combined systems, which optimise the benefits of individual types of equipment and improve overall performance. For example (Figure 5), KnitMesh mist eliminators can be used in combination with Sulzer Mellachevron vane packs or Shell Swirltubes to produce very high separation efficiencies at high gas loadings. By using the KnitMesh mist eliminator as a pre-conditioner for the Mellachevron, it is operated above its normal entrainment or flooding point and consequently liquid is stripped away from the downstream surface. The liquid dispersion reentrained from the mesh mist eliminator has a larger mean diameter and is suitable for subsequent separation by secondary, high capacity equipment. Additional benefits of combined systems include: the ability to design the equipment to provide very high turndown capabilities because at low gas velocities, where high capacity separators tend to be ineffective, the KnitMesh preconditions behave as conventional mist eliminators.

**Sulzer MKS Multi Cassette™**

The Sulzer MKS Multi Cassette separator was designed to provide higher droplet removal efficiency and capacity with lower costs. The MKS consists of an axial inlet cyclone with a succession of separating cassettes mounted above it. The inlet cyclone swirls the gas, thereby causing some of the droplets to be separated initially. This liquid is collected in the bottom cassette and drained. Above the cyclone, the gas, still carrying the remaining entrained droplets, is distributed radially outward to the cassettes. Each cassette is equipped with several layers of wire mesh packing which efficiently separates the remaining droplets by both direct interception (barrier effect) and inertial interception. The liquid collected in each cassette is drained to the next lower cassette by a piping system. Finally, all the liquid is collected at the bottom cassette and then drained downwards out of the device through pipes.

**MKS - Application in Gas Drying Column (Glycol Contractor)**

The drying of natural gas in glycol (often TEG) dehydrators is a widely used and well-established process. However, the use of modern, high-capacity packing such as Sulzer MellapakPlus™ in absorption columns has increased the demands on ancillary equipment as well. In these applications, the droplet size is in the range of 5–25μm. To minimise the carryover, a glycol mist eliminator is required at the top of the column in order to satisfy the stipulated standard of no more than 13.7 litres loss of glycol per million standard cubic metres of gas (0.1 USgal/MMSCF). This loss expressly concerns only the glycol present in liquid form. As a result, a column equipped with high performance packing requires a suitably sized high capacity mist eliminator to meet design gas flow rates. The MKS Multi Cassette mist eliminator ideally combines with Sulzer MellapakPlus in glycol dehydrators to provide proven performance in natural gas drying columns.
generally not recommended for high-pressure applications containing hydrocarbon liquids and tend to have relatively low separation efficiency. Axial cyclones are often the first choice and are optimally designed for these tough conditions, but they also require a higher minimum available installation height in the separator. When converting separators to higher capacity, the available installation height is often limited. Also, modifications inside the column can be restricted because, in general, no additional attachments can be welded directly to the column wall. With the MKS Multi Cassette mist eliminator, Sulzer provides an optimal addition to the category of high-capacity mist eliminator internals.

Shell Swirltube™
Axial flow cyclonic mist eliminators have been widely adopted in hydrocarbon systems where high capacity is important. They are often used in high-pressure applications where the performance of vane packs tends to deteriorate and where mesh mist eliminators are also undesirable because of their limited capacity and therefore large vessel sizes. The Shell Swirltube (Figure 8) is, in essence, a stainless steel tube with a swirler at the inlet and longitudinal slits in the tube wall. Liquid is separated by impaction of droplets and on the tube wall by the centrifugal forces induced by the swirling gas flow.

is also bled through these slits. This gas leaves the liquid collection chamber via the secondary outlets at the top of the Swirldeck assembly. Performance can be improved by using a secondary KnitMesh mist eliminator to separate entrainment from the gas leaving the secondary outlets. The main fraction of the gas leaves the Swirltube via the primary gas outlet at the top. Drain pipes guide the liquid, collected in the space between the tubes and on the upper cover of the Swirldeck, to below the liquid level.

Scaling-up of a separator equipped with a Swirldeck is done simply by increasing number of Swirltubes proportional to the gas flow in the separator.

Selection of separation technologies is function of the dispersed liquid phase concentration, droplet size and the required separation efficiency. Their typical application window is for separation of liquid/gas or three-phase liquid/liquid/gas mixtures.

Re-entrainment of this liquid is prevented by draining the film via the slits to the liquid collection chamber outside the tube. To ensure the proper functioning of the Swirltube, it is essential that some gas

Shell High Capacity Separators
Shell proprietary high-capacity gas/liquid separators, such as Shell SVS™, SMS™, SMSM™ and SMMSM™ separators, combine the best features of the separation products from Sulzer Chemtech portfolio. Shell gas/liquid separators combine Schoepentoeter, KnitMesh and Swirldeck separation technologies in a single vertical vessel drum.

Selection of separation technologies is function of the dispersed liquid phase concentration, droplet size and the required separation efficiency. Their typical application window is for separation of liquid/gas or three-phase liquid/liquid/gas mixtures.

When a high capacity and high separation efficiency is required, SMS (M) technology is the lowest weight and volume solution for phase separation offshore and onshore. It gives up to 2.5 times more capacity compared to a conventional KnitMesh mist eliminator without vessel replacement. Shell SMS, SMSM and SMMSM gas/liquid separators (Figure 7) are named after the configuration of the different internals used for each type of separator:

- Schoepentoeter or Schoepentoeter Plus (S) - used as feed inlet device for vapour distribution with bulk liquid removal
- KnitMesh (M) - which acts as coalescer and separator, depending on the gas flow rate
- Double Primary KnitMesh (MM) - specially developed for applications with two immiscible liquid phases in the feed to the separators (such as glycol/condensate in Dew-Point Separators)
- Swirldeck (S) - comprising multiple Swirltubes.
- A second KnitMesh (M) is used downstream of the Swirldeck in SMSM gas/liquid separators for demisting secondary gas.

In fouling or waxy service, the KnitMesh can be replaced by a Sulzer Mellachevron vane pack (SVS systems).
